**ABSTRACT**

Engineered combinatorial libraries derived from small protein scaffolds represent a powerful tool for generating novel binders with high affinity, required specificity and designed inhibitory function. This work was aimed to generate a collection of recombinant binders of human interleukin-23 receptor (IL-23R), which is a key element of proinflammatory IL-23-mediated signaling. A library of variants derived from the three-helix bundle scaffold of the albumin-binding domain (ABD) of streptococcal protein G and ribosome display were used to select for high-affinity binders of recombinant extracellular IL-23R. A collection of 34 IL-23R-binding proteins (called REX binders), corresponding to 18 different sequence variants, was used to identify a group of ligands that inhibited binding of the recombinant p19 subunit of IL-23, or the biologically active human IL-23 cytokine, to the recombinant IL-23R or soluble IL-23R-IgG chimera. The strongest competitors for IL-23R binding in ELISA were confirmed to recognize human IL-23R-IgG in surface plasmon resonance experiments, estimating the binding affinity in the sub- to nano-molar range. We further demonstrated that several REX variants bind to human leukemic cell lines K-562, THP-1 and Jurkat, and this binding correlated with IL-23R cell-surface expression. The REX125, REX009 and REX115 variants competed with the p19 protein for binding to THP-1 cells. Moreover, the presence of REX125, REX009 and REX115 variants significantly inhibited the IL-23-driven expansion of IL-17-producing primary human CD4+ T-cells. Thus, we conclude that unique IL-23R antagonists derived from the ABD scaffold were generated that might be useful in designing novel anti-inflammatory biologicals.

**Key words:** cytokine; psoriasis; engineered binding protein; protein scaffold; combinatorial library; ribosome display.

**INTRODUCTION**

Autoimmune diseases such as psoriasis, Crohn’s disease, rheumatoid arthritis, or multiple sclerosis have recently been found to be associated with IL-23-mediated signaling promoted by IL-23 receptor-expressing Th17 and other lymphocyte subsets.1–7 In these cell types, dendritic cell-released IL-23 cytokine, consisting of a unique p19 subunit and a common p40 subunit shared with IL-12,8,9 activates signaling via interaction of the p19 subunit with its cognate cell surface receptor, IL-23R, while the p40 subunit of IL-23 binds to IL-12 receptor β110,11 (Fig. 1). Synergistic tethering of the IL-23 heterodimer to both receptor units leads to receptor heterodimerization fol-

lowed by quaternary complex formation and triggering of the Jak/Stat signaling cascade, involving Jak2, Tyk2, Stat1, Stat3, Stat4, and Stat5. Transduction of signal activates the transcription machinery and results in secretion of a cocktail of inflammatory modulators such as IL-17A, IL-17F, IL-22, and of certain chemokines that stimulate keratinocytes and other cell types, thereby playing a pivotal role in pro-inflammatory processes (reviewed in Ref. 12).

Efficient therapeutic intervention, preventing hyperproliferation of keratinocytes in clinical manifestations of psoriasis, depends on the blockade of interaction between p19/p40 subunits of IL-23 and their cognate cell membrane receptors. Recently it has been demonstrated that monoclonal antibody-based drug Stelara (ustekinumab, Janssen Biotech), blocking the p40 subunit of IL-23 and preventing it from the interaction with IL-12 receptor β1, reached an excellent efficacy in the treatment of medium to severe form of psoriasis. However, this drug inhibits the binding of the common p40 subunit, shared both by IL-12 and IL-23, and thus interferes with two different signaling pathways. This often leads to complications, including cardiovascular side effects or higher risk of cancer development. Novel therapeutic strategies, therefore, require development of novel IL-23R antagonists that will separate IL-23-mediated signaling from the IL-12 cascade, thus preserving T(H)-1 cell differentiation and immunity. Recently, anti-p19 specific antibodies MK-3222 (Merck), CNTO 1959 (Janssen Biotech) and AMG 139 (Amgen/MedImmune) have been developed.

As an alternative to conventional monoclonal antibody-based drugs, artificial ligands derived from small protein scaffolds attract attention as robust diagnostic probes and next generation protein therapeutics. Among different structure-instructed approaches, three-helix bundle scaffolds have recently demonstrated sufficient thermal stability, solubility and mutability for being used as a proof-of-concept domain suitable for generation of highly complex combinatorial libraries. The well-established Affibody molecules originally selected from Protein A domain-Z-based libraries by phage display selection approaches are currently being used as practical binders for in vitro detection, in vivo diagnostics or high-affinity bioanalytical procedures. Preservation of folding function together with easy scaffold modifications and low molecular weight, allowing excellent tissue penetration, move the Affibody-derived binders close to the therapeutic use.

The albumin-binding domain of streptococcal protein G is another example of three-helix bundle scaffold being successfully used for the construction of combinatorial libraries. Recently we have demonstrated that randomization of 11 residues of a flat helical surface, formed by two helices with an inter-link loop (Fig. 2), was sufficient to yield a combinatorial library of a theoretical complexity of $10^{16}$ codon variants that was then successfully used for the selection of high-affinity binders of human IFN-γ. In this type of library, natural HSA-binding affinity of the ABD domain was compromised in favor of newly engineered affinity for the chosen target. Alternatively, another group randomized 11 residues of a different ABD scaffold surface to generate a combinatorial library that yielded new affinity yet preserved the original HSA binding. This type of “dual-affinity library” was used to select binders of human TNF-α and ErbB3.

IL-23 receptor belongs to the class-I cytokine receptor family and shares typical features with tandem fibronectin-type III (FnIII) domains containing a hallmark pattern of disulfide bonds and WQPWS sequence tag similar to a conserved WSXWS cytokine receptor consensus located in the transmembrane-proximal FnIII domain. Both domains form a cytokine-binding homology region (CHR) which, in concert with a terminal Ig-like domain, is believed to play a substantial role in IL-23 binding.

The molecular structure of the IL-23/IL-23R complex is not available yet, therefore, designing efficient inhibitors of IL-23 function with a promising therapeutic
potential remains cumbersome. Here we describe generation of a set of novel recombinant antagonists of the human IL-23 receptor. Their inhibitory potency on IL-23 function is demonstrated on several arrangements of in vitro binding assays, cell-surface competition experiments and ex vivo functional assays. Our data further document that the three-helix bundle scaffold of ABD is suitable for development of anti-inflammatory IL-23 receptor-based next generation therapeutics.

MATERIALS AND METHODS

Antibodies and detection agents

Monoclonal antibodies (mAbs) anti-human IL-23R-allophycocyanin (APC) (mouse IgG2b) specific for the human IL-23 receptor and IgG2b isotype control-APC (mouse IgG2b) were obtained from R&D Systems, Minneapolis, MN. Mouse anti-p19 mAb was purchased from Biolegend, San Diego, CA. Cy5-conjugated goat anti-mouse IgG (F(ab')2 fragment) was obtained from Jackson ImmunoResearch Laboratories, West Grove, PA. Streptavidin-phycoerythrin was purchased from eBioscience, San Diego, CA.

Cell lines and growth conditions

The cell lines used in the experiments were a human acute monocytic leukemia cell line, THP-1 (ATCC number: TIB-202), a human leukemic cell line, K562 (ATCC number: CCL-243) and a human T-cell lymphoma cell line, Jurkat (ATCC number: TIB-152). The cells were grown in RPMI-1640 medium (Sigma-Aldrich, St. Louis, MO) supplemented with 10% fetal calf serum (FCS) (GIBCO, Grand Island, N.Y.) and antibiotic-antimycotic solution (ATB) (Sigma-Aldrich, St. Louis, MO).

Production of recombinant IL-23R

cDNA coding for the extracellular part (fragment Gly24-Asn350) of the human IL-23 receptor (IL-23R, GenBank: AF461422.1) was amplified by PCR using forward primer IL23Rex-F-Nco-his (ATTACCATGGGCAGCCACCATCATCATCATCAGCAGCGGAATTACAAAATATAAACTGCTCTGG), containing the start codon and the His6-tag sequence, and a reverse primer IL23Rex-R-Xho (GGGCACCTTACTTCTGACAACGTGAC TCGAGATAT) bearing the TGA stop codon. The resulting PCR product was inserted into the pET-28b vector (Novagen, Germany) using Ncol and Xhol cloning sites and introduced into Escherichia coli TOP10 cells. The obtained plasmid was used for exIL-23R protein production in E. coli SHuffle strain (SHuffle® T7 Express Competent E. coli, New England Biolabs, Ipswich, MA). Bacteria were grown in liquid LB media with kanamycin (60 µg/L) at 30°C, induced with 1 mM isopropyl-β-d-thiogalactopyranoside (IPTG). The exIL-23R protein was extracted from isolated inclusion bodies with 8M urea in TN buffer (50 mM Tris, 150 mM NaCl, pH 8.0) and purified by Ni-NTA affinity chromatography.

For protein production targeted into bacterial periplasm, the exIL-23R cDNA was inserted downstream of the peB leader sequence into the pET-26b vector (Novagen, Germany) using the same restriction sites as above and introduced into the E. coli BL21 (DE3) strain. The LB broth culture with kanamycin (60 µg/L) was grown at 30°C to reach cell density OD600 = 1.0, protein production was induced by 1 mM IPTG, and protein was harvested after 4 h. The resulting expression led to the production of an insoluble protein that was extracted after the sonication by 8M urea in the TN buffer and purified on a Ni-NTA column.

Production of recombinant p19 subunit of IL-23

The DH-p19 recombinant form of the p19 subunit of IL-23 (calculated Mw 23.3 kDa) was produced in fusion to an N-terminal double-His6-TEV purification tag containing the TEV protease consensus cleavage site.
Synthetic, codon-optimized p19 cDNA (GENEART, Germany) was inserted into the PET-28b vector as a NcoI-XhoI fragment and the DH-p19 protein was produced in E. coli BL21 (DE3) host cells. The DH-p19 protein was extracted from inclusion bodies and purified in Ni-NTA agarose.

Alternatively, soluble p19 protein was produced in the form of a protein fusion to maltose-binding protein (MBP) carrying a double-His$_6$-tag at the N-terminus (DH-MBP-p19, calculated $M_w$ 69 kDa). Primers p19-F-Nhel (GGGCTAGC TACCCAGGCTCGTCGGGGGC) and p19-R-Xhol (GGGCCCTGAGGGACTACGGTTGTC GCTCGTCACTAACAGAGAACTTGACA) were used to amplify DNA encoding p19 for insertion into a pET28b-derived vector into which sequences coding for double-His$_6$-MBP-TEV-MCS-TEV-His$_6$ were introduced. The double-His$_6$-MBP-TEV-p19-TEV-His$_6$ fusion protein was produced in the cytoplasmic fraction of E. coli BL21 (DE3) cells and purified on a 5 mL His-Trap column using ÄKTA purifier (GE Healthcare, UK) and stepwise gradient of 250, 500, and 1000 mM imidazole.

**Test of the binding activity of exIL-23R and p19 by ELISA**

The recombinant extracellular portion of the IL-23 receptor (exIL-23R) or the p19 protein were immobilized directly on the NUNC Polysorp 96-well plate surface in coating buffer (100 mM bicarbonate/carbonate solution, pH = 9.6) at a concentration of 5 to 10 µg/mL at ~7°C overnight. The plate was washed with PBS buffer containing 0.05% Tween (PBST) and blocked by 1% BSA in the same buffer (PBSTB). Serial dilutions of purified DH-MBP-p19 or DH-p19 recombinant proteins were prepared in PBSTB buffer and p19 binding was detected using mouse anti-human IL-23 (anti-p19) polyclonal antibody followed by goat anti-mouse IgG horseradish peroxidase (HRP) conjugate (BioLegend, San Diego, CA), both diluted in PBSTB 1:1000. exIL-23R binding to immobilized DH-MBP-p19 was detected using goat anti-IL-23R monoclonal antibody (1:250) followed by secondary rabbit anti-goat HRP conjugate (1:1000) (R&D Systems, Minneapolis, MN). OPD substrate (Sigma-Aldrich, St. Louis, MO) was used as HRP substrate in citrate buffer (3.31% sodium citrate trisac buffer, phosphoric acid, pH = 5.0), reactions were stopped with 2M sulfuric acid and absorbance was read at 492 nm.

**ABD library construction and ribosome display selection of REX binders**

Combinatorial DNA library was generated as described previously.34 HPLC-purified synthetic oligonucleotides were used. The forward primer ABDLIB-setB1c (5’-TTAGGAGCTAAAGTCTTAGCTACACGAGACCTGACA ATATGGGATTAAGTGC-3’) and the reverse primer setB-rev (5’-ACCGCCGATCCAGGTAA-3’) were used for PCR. The latter had distinct codons randomized at defined positions (5’-ACCGCCGATCCAGGTAA-3’).

Alternatively, soluble p19 protein was produced in the form of a protein fusion to maltose-binding protein (MBP) carrying a double-His$_6$-tag at the N-terminus (DH-MBP-p19, calculated $M_w$ 69 kDa). Primers p19-F-Nhel (GGGCTAGC TACCCAGGCTCGTCGGGGGC) and p19-R-Xhol (GGGCCCTGAGGGACTACGGTTGTC GCTCGTCACTAACAGAGAACTTGACA) were used to amplify DNA encoding p19 for insertion into a pET28b-derived vector into which sequences coding for double-His$_6$-MBP-TEV-MCS-TEV-His$_6$ were introduced. The double-His$_6$-MBP-TEV-p19-TEV-His$_6$ fusion protein was produced in the cytoplasmic fraction of E. coli BL21 (DE3) cells and purified on a 5 mL His-Trap column using ÄKTA purifier (GE Healthcare, UK) and stepwise gradient of 250, 500, and 1000 mM imidazole.

**Test of the binding activity of exIL-23R and p19 by ELISA**

The recombinant extracellular portion of the IL-23 receptor (exIL-23R) or the p19 protein were immobilized directly on the NUNC Polysorp 96-well plate surface in coating buffer (100 mM bicarbonate/carbonate solution, pH = 9.6) at a concentration of 5 to 10 µg/mL at ~7°C overnight. The plate was washed with PBS buffer containing 0.05% Tween (PBST) and blocked by 1% BSA in the same buffer (PBSTB). Serial dilutions of purified DH-MBP-p19 or DH-p19 recombinant proteins were prepared in PBSTB buffer and p19 binding was detected using mouse anti-human IL-23 (anti-p19) polyclonal antibody followed by goat anti-mouse IgG horseradish peroxidase (HRP) conjugate (BioLegend, San Diego, CA), both diluted in PBSTB 1:1000. exIL-23R binding to immobilized DH-MBP-p19 was detected using goat anti-IL-23R monoclonal antibody (1:250) followed by secondary rabbit anti-goat HRP conjugate (1:1000) (R&D Systems, Minneapolis, MN). OPD substrate (Sigma-Aldrich, St. Louis, MO) was used as HRP substrate in citrate buffer (3.31% sodium citrate trisac buffer, phosphoric acid, pH = 5.0), reactions were stopped with 2M sulfuric acid and absorbance was read at 492 nm.

**ABD library construction and ribosome display selection of REX binders**

Combinatorial DNA library was generated as described previously.34 HPLC-purified synthetic oligonucleotides were used. The forward primer ABDLIB-setB1c (5’-TTAGGAGCTAAAGTCTTAGCTACACGAGACCTGACA ATATGGGATTAAGTGC-3’) and the reverse primer setB-rev (5’-ACCGCCGATCCAGGTAA-3’) were used for PCR. The latter had distinct codons randomized at defined positions (5’-ACCGCCGATCCAGGTAA-3’).
of a ribosome display selection campaign, were obtained and cloned as NcoI and XhoI fragments in the pET-28b vector containing an in-frame inserted full length tolA DNA sequence. Later, the AviTag in vivo biotinylation sequence (GLNDIFEAQKIEWHE) was added to the C-terminus of the TolA spacer to allow biotinylated protein detection by streptavidin. The AviTag sequence was introduced using PCR with forward primer EWT5-ABDfor1 and reverse primer tolA-AVIrev1 (TTTCCGCT CGAAGCTATTCTGCGATTTTCTAGGCTCGAA GATGTCTTTACGGCCGTGAATCTCGGCGC). The final His<sub>6</sub>-REX-TolA-AVI fusion proteins were produced and purified in the same way as REX variant-produced E. coli strain as previously described, where appropriate REX recombinant variant produced in E. coli BL21 (DE3) BirA strain expressing biotin ligase (BirA) in the presence of 50 μM d-biotin in the LB medium and following induction with 2 mM IPTG. The soluble proteins were purified from cell extracts on Ni-NTA agarose columns.

For all binding assays, a control TolA fusion protein with the original albumin binding domain (ABDwt) was used as a negative control. To construct ABDwt with TolA and AviTag sequences (His<sub>6</sub>ABDwt-TolA-AVI), PCR amplification with ABDwt-tolA plasmid DNA as a template and forward primer EWT5-ABDfor1 (as mentioned above) and reverse primer ABDrev (TTACTAG-GATCCAGTTACGTGATTTTCTAGGCTCGAA GATGTCTTTACGGCCGTGAATCTCGGCGC) was used. The amplified PCR product was digested by NcoI and BamHI enzymes and ligated into the pET-28b vector carrying amplified PCR product was digested by

**Screening of IL-23R-binding REX variants by ELISA**

For binding assays, selected clones were picked, the inserted sequence was verified by DNA sequencing and proteins were produced in the E. coli BL21 (DE3) BirA strain as previously described, where appropriate REX proteins purified on Ni-NTA columns were used. Two different sandwich layouts were used for the binding assays. In the first case, NUNC Polysorp plates were coated directly with exIL-23R protein (5 μg/mL, recombinant variant produced in E. coli SHuffle strain) in coating buffer at low temperature (∼7°C) overnight and the washed plates were blocked by PBSTB. The serially diluted cell lysates or purified REX proteins were applied in PBSTB and the amount of bound biotinylated REX proteins was detected using streptavidin Poly-HRP conjugate (1:5000). In the second setup, the plates were coated with streptavidin (1 μg/mL) in coating buffer, and biotinylated REX proteins (5 μg/mL) were immobilized through binding to streptavidin. Serially diluted exIL-23R in PBSTB was added into the wells and receptor binding to immobilized REX variants was detected by goat anti-IL-23R polyclonal antibody (1:250) sandwich with secondary rabbit anti-goat HRP conjugate (1:1000, R&D Systems, Minneapolis, MN).

**Sequence analysis and clustering of selected REX variants**

DNA constructs of selected clones expressing full-length REX variants were sequenced. Amino acid multiple sequence alignment of all selected clones and construction of the similarity tree were performed using the ClustalW program. The tree is presented as a phenogram rendered by the Phylogendron online service (http://iubio.bio.indiana.edu/treeapp).

**Competition ELISA assay**

Maxisorp or Polysorp plates (NUNC, Denmark) were coated with recombinant H-exIL-23R or pelB-exIL-23R and binding of DH-MBP-p19 or DH-p19 as analytes was detected using antibodies as above. Alternatively, plates were coated with DH-MBP-p19 or DH-p19 and binding of IL-23R variants was detected using the corresponding antibodies: 20 nM DH-MBP-p19, 50 nM DH-p19, and 60 nM exIL-23R or pelB-exIL-23R in PBSTB were used as constant concentrations of analytes in the experiments where the concentration of the competitor REX binders varied. Three of the best inhibitory variants, REX125, REX115, and REX009, were examined for binding to immobilized recombinant human IL-23R-IgG chimera (R&D Systems, Minneapolis, MN), produced as soluble and glycosylated protein secreted by a mouse myeloma cell line. A Polysorp plate was coated with 1 to 2 μg/mL IL-23R-IgG chimera diluted in coating buffer, and 20 nM DH-MBP-p19 protein or 23 nM human IL-23 (R&D Systems, Minneapolis, MN) were used to compete with REX ligands.

**Fluorescence-based thermal-shift assay**

Protein samples (0.1 mg/mL) in HEPES, and 5x Sypro Orange dye (Sigma-Aldrich, St. Luis, MO) were added into 25 μL total volume. Using the real-time PCR Detection System CFX96 Touch (Bio-Rad Laboratories), the proteins were incubated in a thermal gradient from 20°C to 80°C at increments of 0.5°C and with 30 s-hold intervals. The degree of protein unfolding was monitored by the FRET (fluorescence resonance energy transfer) channel that captured the spectral properties of Sypro Orange unfolded protein complexes (excitation wavelength ≈470 nm and emission wavelength ≈570 nm). The data were analyzed by CFX Manager software and the melting temperatures were determined using the first derivative spectra.

**Surface plasmon resonance measurement**

Surface plasmon resonance measurements were carried out using custom SPR biosensors (Institute of Photonics...
and Electronics, Prague, Czech Republic) with four independent sensing spots.\textsuperscript{32} The REX proteins were immobilized to the SPR chip using the protocol described in Ref. 38. Briefly, the SPR sensor chip was coated with self-assembled monolayer of HSC\textsubscript{11}(EG\textsubscript{2})\textsubscript{2}-OH and HSC\textsubscript{11}(EG\textsubscript{1}-G\textsubscript{1})\textsubscript{2}OCH\textsubscript{3}COOH alkenethiols. The functionalized SPR chip was mounted to the SPR sensor and all the subsequent molecular interactions were monitored in real-time at temperature 25°C and flow rate 30 \(\mu\text{L}/\text{min}\). The REX009, REX125 and ABDwt proteins were diluted in SA buffer (10 mM sodium acetate, pH 5.0 at 25°C) at 5 \(\mu\text{g}/\text{mL}\) concentration. Each protein was immobilized to a separate sensing spot via amide-bond-forming chemistry. The noncovalently bound proteins were then washed away with a buffer of high ionic strength (PBS\textsubscript{Na}: 1.4 mM KH\textsubscript{2}PO\textsubscript{4}, 8 mM Na\textsubscript{2}HPO\textsubscript{4}, 2.7 mM KCl, 0.75M NaCl, pH 7.4 at 25°C). The remaining carboxylic groups were deactivated with 5-min injection of 1M ethanolamine-hydrochloride (pH 8.5). After a baseline was established in the SA buffer, the solution of IL23-R was pumped in the sensor for 10 min. The measurement was repeated on three different chips. The interaction kinetics was compensated for reference sensor response (measured in channel with ABD\textsubscript{wt}) and analyzed with BiaEvaluation software (GE Healthcare, Uppsala, Sweden).

### Detection of cell surface IL-23R and binding of REX variants, p19 or IL-23 to the surface of cultured human cells

All binding assays were performed in HBSS buffer (10 mM HEPES, pH 7.4, 140 mM NaCl, 5 mM KCl) complemented with 2 mM CaCl\textsubscript{2}, 2 mM MgCl\textsubscript{2} and 1% (v/v) FCS (cHBSS) in 96-well culture plates (Nunc, Roskilde, Denmark).

For staining of the IL-23R molecules on the cell surface, 5 \(\times\) 10\textsuperscript{5} cells were incubated for 30 min at 4°C in 50 \(\mu\text{L}\) of cHBSS buffer containing anti-human IL-23R-APC (1:5 dilution) or isotype control-APC (1:5 dilution) mAbs. For REX binding assay, 5 \(\times\) 10\textsuperscript{5} cells were incubated in 100 \(\mu\text{L}\) of cHBSS with biotinylated REX binders or ABDwt controls (10 \(\mu\text{g}/\text{mL}\)) for 30 min at 4°C, washed with cHBSS, and the cell-bound biotinylated REX-ToLA-AVI or ABDwt-ToLA-AVI was stained with streptavidin-phyceroerythrin conjugate (dilution 1:400) for 30 min at 4°C. For DH-p19 binding assay, 5 \(\times\) 10\textsuperscript{5} cells were incubated in 100 \(\mu\text{L}\) of cHBSS with or without DH-p19 (10 \(\mu\text{g}/\text{mL}\)) for 30 min at 4°C. The cells were washed with cHBSS and the cell-bound DH-p19 was stained with mouse anti-p19 mAb (1:5 dilution) for 30 min at 4°C and after washing with goat anti-mouse IgG antibody labeled with Cy5 (1:50 dilution) for 30 min at 4°C.

Cells were washed, resuspended in 100 \(\mu\text{L}\) of HBSS and analyzed by flow cytometry in a FACS LSR II instrument (BD Biosciences, San Jose, CA) in the presence of 5 \(\mu\text{g}/\text{mL}\) of propidium iodide. Appropriate gating was used to exclude cell aggregates and dead cells and binding data were deduced from the mean fluorescence intensities (MFI).

### Competition between DH-p19 and REX ligands for binding to THP-1 cells

For blocking of REX binding to the IL-23 receptor molecule by DH-p19, THP-1 cells (2 \(\times\) 10\textsuperscript{5}) were preincubated for 15 min at 4°C in the presence of serially-diluted DH-p19 in 50 \(\mu\text{L}\) of cHBSS buffer. Biotinylated REX-ToLA-AVI clones (or ABDwt-ToLA-AVI negative control) were added to the cells in the continuous presence of DH-p19 in 50 \(\mu\text{L}\) of cHBSS buffer to a final concentration of 13 nM and incubated at 4°C for 30 min. The cells were washed with cHBSS and the bound biotinylated REX ligands or ABDwt were detected by streptavidin-phyceroerythrin conjugate (dilution 1:400) for 30 min at 4°C. Cells were washed, resuspended in 100 \(\mu\text{L}\) of HBSS and analyzed by flow cytometry as described above.

### IL-23-dependent ex vivo expansion of human IL-17-producing T-cells in PBMC suspensions

Peripheral blood drawn into EDTA-containing tubes was used to obtain purified mononuclear cells (PBMCs) on Ficoll-Paque gradients (Pharmacia, Uppsala, Sweden). PBMCs were washed once with PBS and resuspended in complete RPMI 1640 media (RPMI 1640 supplemented with 10% heat-inactivated FCS, 100 U/mL penicillin, 100 \(\mu\text{g}/\text{mL}\) streptomycin sulfate and 1.7 mM sodium glutamate). PBMCs were adjusted to 2 \(\times\) 10\textsuperscript{6} cells/mL and activated on a 96-well plate pre-coated with anti-CD3 (MEM-57, 10 \(\mu\text{g}/\text{mL}\), Exbio Praha a.s., Praha, Czech Republic) in the presence of co-stimulatory antibodies against CD28 and CD49d (1 \(\mu\text{g}/\text{mL}\), BD Biosciences, San Jose, CA), in the presence of IL-23 (10 ng/mL) and IL-17R-A (100 U/mL). REX009, REX115, REX125, REX128 binders (7 \(\mu\text{g}/\text{mL}\)) or control ABDwt were added and cells were incubated for three days at 37°C. After overnight rest at 37°C, cells were re-stimulated again (as above) for 6 h at 37°C (last 4 h exocytosis was blocked with Brefeldin A (10 \(\mu\text{g}/\text{mL}\), Sigma-Aldrich). Next, cells were stained with antibodies to CD8 Horizon V-500 (BDB) or CD8 (PerCP-Cy5.5, eBioscience, San Diego, CA), for CD4 (ECD, Immunotech, Marseille, France) and with antibodies for IFN-\gamma (PE Cy7), IL-2 (APC), IL-17 (PB) (eBioscience) and CD154 (PE, Immunotech). Cells were washed again and measured in flow cytometry BD FACs Aria III (BDB). Absolute cell counts were obtained using BD Truecount.
RESULTS

Production of recombinant human IL-23R and p19 proteins

The human IL-23 receptor gene consists of 10 exons that code for a 629 amino acid-long transmembrane receptor molecule. For the purpose of being used as a target in ribosome display selection of ABD scaffold-derived ligands, we produced a recombinant form of the extracellular domain of IL-23R (exIL-23R) comprising the residues 24 to 350. This part of IL-23R contains five cysteine pairs encoded within sequences forming both fibronectin type III and terminal Ig-like domains. Therefore, the E. coli SHuffle strain supporting formation of disulphide bridges in bacterial cytoplasm was used to express the N-terminally His6-tagged IL-23R (H-exIL-23R). The protein was extracted with 8 M urea from inclusion bodies formed in bacterial cells. Alternatively, we cloned the same receptor cDNA fragment into the pET-26b vector containing a periplasm-targeting pelB leader sequence (pelB-exIL-23R) comprising the residues 24 to 350. This part of IL-23R contains five cysteine pairs encoded within sequences forming both fibronectin type III and terminal Ig-like domains. Therefore, the E. coli SHuffle strain supporting formation of disulphide bridges in bacterial cytoplasm was used to express the N-terminally His6-tagged IL-23R (H-exIL-23R). The protein was extracted with 8 M urea from inclusion bodies formed in bacterial cells. Alternatively, we cloned the same receptor cDNA fragment into the pET-26b vector containing a periplasm-targeting pelB leader sequence (pelB-exIL-23R) and expressed the receptor in E. coli BL21 (DE3) strain. However, the protein was also produced as insoluble fraction and was, therefore, refolded from urea-containing extracts. Both proteins were affinity-purified by Ni-NTA chromatography and refolded by dilution from urea-containing extracts. Both proteins were affinity-purified by Ni-NTA chromatography and refolded by dilution from urea-containing extracts. The identity of the proteins was confirmed by Western blots using anti-His and anti-IL-23R antibodies (data not shown).

For studies of the interactions between IL-23R and IL-23 cytokine, we also produced a recombinant form of the 170 amino acid residue-long p19 subunit of human IL-23. A 23 kDa fusion p19 protein, consisting of a mature portion of p19 with an N-terminal double-polyhistidinyl tag (DH-p19), was produced into inclusion bodies in E. coli cells, extracted with 8 M urea, and DH-p19 was affinity purified by Ni-NTA chromatography. Its identity was confirmed by detection with anti-IL-23 antibody on Western blots (data not shown).

In search for solubility-mediating modifications of the p19 protein using several different solubility-supporting fusion tags, the maltose-binding protein (MBP) in combination with a C-terminal modification were found to support the solubility of the produced p19-MBP fusion protein as the only found variant. In this case, the 69 kDa N-terminally double-His6-MBP-p19 fusion protein contained a C-terminal prolongation, installing an additional 40 aa solubility-supporting sequence (LEKKTCTSR A5STTTTETEILITKPERKLSSLWLLPPSNN). Yet this modification was found unintentionally, all other tested C-terminal modifications, including removal of this sequence by a stop codon termination and replacement by a single-his tag, Streptag or FLAG tag sequence consensus, converted the DH-MBP-p19 protein into the insoluble form. Therefore, this soluble version of p19 was used for further studies as an affinity purified product.

To verify that the recombinant refolded exIL-23R protein still bound the recombinant form of the p19 subunit, ELISA experiments with immobilized exIL-23R were performed. As shown in Figure 3, both the refolded DH-p19 protein and the soluble purified DH-MBP-p19 specifically bound to immobilized H-exIL-23R in a saturable manner. This was further confirmed in a reversed setup where the coated DH-MBP-p19 or refolded DH-p19 protein bound the refolded soluble H-exIL-23R protein (data not shown). These data suggested that the refolded recombinant exIL-23R protein maintained the capacity to specifically bind the p19 subunit of IL-23. Therefore, this protein could be used as a target in ribosome display for selection of IL-23R-specific binders derived from the ABD scaffold.

Ribosome display selection of human IL-23R binders

Recently we have demonstrated that randomization of 11 residues in the ABD domain scaffold was sufficient for identification of binders of human interferon-γ with nanomolar range of affinity.34 We therefore used the same approach for the generation of a combinatorial ABD library of a theoretical complexity of 1014 protein variants (Fig. 2). In combination with ribosome display screening, we identified a collection of binders raised against recombinant H-exIL23R. To be able to produce in vivo biotinylated ABD variants required for verification of their binding affinity to H-exIL-23R by ELISA, ABD variants found after three- or five-round selection campaigns (called REX binders) were modified by installing the AviTag sequence downstream of TolA C-terminus. ELISA-positive cell lysates of REX-TolA-AVI clones were selected for further analysis using Western blots. DNA sequences of 34 REX binders were sequentially analyzed and their amino acid sequence similarity compared. As shown in Figure 4, we identified 18 different REX variants, but displaying significant sequence redundancy. All 18 biotinylated REX-TolA-AVI proteins were purified in Ni-NTA agarose and the binding affinity to both immobilized H-exIL-23R and pelB-H-exIL-23R receptor proteins was analyzed using ELISA (data not shown). Analysis of several ELISA-negative REX-TolA-AVI variants by restriction digestion and DNA sequencing revealed that these clones lack the ABD cDNA sequence, thus forming the spliced REX version His6-TolA-AVI. One of such clones, called AABD, was purified and used for further experiments as another important negative control over the original His6-ABDwt-TolA-AVI.
Identification of inhibitory REX variants

Based on the results of binding assays performed for all 18 different REX-ToLA-AVI variants, 15 clones of the complete REX collection were investigated for their ability to inhibit p19/IL-23 binding. To this goal, we used competition ELISA with the immobilized H-exIL-23R and a constant amount of DH-MBP-p19 as an analyte, spiked with an increasing level of the REX-ToLA-AVI variants. We found that 11 of the 15 tested REX variants inhibited p19 binding in the micromolar to nanomolar concentration range. The results of the competition ELISA for the four best REX variants are presented in Figure 5. For these inhibitory variants, the sequence similarity comparison is documented in Table I. Sequence analysis of all tested variants indicated that two of the inhibitory variants, REX001 and REX009, contain one cysteine residue in the 11 randomized positions.

To further confirm the inhibitory potency of the REX binders, we performed competition ELISA with a different receptor-cytokine protein pair. REX inhibitors found in the previous setup of the competition ELISA also inhibited binding of the DH-p19 protein to the coated pelB-H-exIL-23R (not shown). In correlation with the result shown in Figure 5, all tested REX binders were found to suppress the p19 binding. To verify that the found competition potency of the tested REX clones can be attributed to the specific binding of the REX proteins to the refolded receptor molecule rather than to non-specific or misfolded protein binding, we performed additional competition assays with the same protein pairs but in the opposite ELISA layouts in which DH-MBP-p19 or DH-p19 were immobilized on the plastic plate. These results did confirm previous data (not shown).

To investigate whether inhibitory REX binders recognize the soluble and glycosylated form of IL-23R, we performed ELISA experiments with a commercial product of recombinant human IL-23R-IgG chimera (R&D Systems), secreted by an NS0-derived murine myeloma cell

Figure 3
Recombinant extracellular IL-23 receptor binds the recombinant p19 subunit of IL-23. (a) The extracellular portion (residues 24 to 350) of human IL-23 receptor was expressed in E. coli SHuffle cells, purified and refolded from 8M urea extracts of inclusion bodies and coated on ELISA plates. Binding of soluble DH-MBP-p19 fusion protein or of refolded DH-p19 protein to immobilized receptor was detected by anti-human IL-23 (p19) polyclonal antibody sandwich with secondary anti-IgG-HRP. Error bars represent standard deviations. (b) SDS-PAGE of DH-p19 (lane 1) and DH-MBP-p19 (lane 2). The DH-p19 and DH-MBP-p19 proteins were purified from E. coli cell lysates on Ni-NTA and separated on 12.5% polyacrylamide gel stained by Coomassie blue. M indicates the protein marker.

Figure 4
Similarity tree of polypeptide sequences of the obtained REX variants binding exIL-23R. Sequence analysis of 34 cloned REX binders of exIL-23R obtained by ribosome display selection revealed 18 unique sequence variants. For similarity analysis, only the sequences between residues 20 and 46 were compared, as the N-terminal amino acid positions 1 to 19 were nonrandomized.
line. As shown in Figure 6, increasing concentration of REX125, REX115, and REX009 binders decreased the binding of DH-MBP-p19 to the immobilized IL-23R-IgG. A similar inhibitory effect of the REX binders was also found for the recombinant Sf 21 (baculovirus)-derived human single-chain IL-23 (R&D Systems) (not shown). Thus, we conclude that we identified REX variants with the ability to suppress p19/IL-23 binding to IL-23R, as demonstrated in several layouts of direct ELISA.

Biophysical characterization of REX inhibitors

SPR biosensor binding analysis was used to further characterize the binding interactions between IL-23R and the REX ligands. The chip of a 4-channel SPR biosensor was functionalized with self-assembled monolayer of alkanethiols, to which His6-REX-TolA-AVI and His6-ABDwt-TolA-AVI proteins were attached. The response to IL-23R-IgG chimera interaction of such SPR biosensor is shown in Figure 7 for sensor surfaces functionalized with REX125, REX009 and control ABDwt proteins, respectively. Error bars are shown as standard deviations.

Parental nonmutated ABD (ABDwt) of streptococcal protein G (G148_GA3) was aligned with the randomized portions of sequenced REX clones that were selected in ribosome display for IL-23R binding and belong to the best binders. Grey boxes indicate the 11 positions at which the residues of ABD (aa 20 to 46) were randomized. The dark box marks an unintended mutation I38L found in REX128. In the nonrandomized N-terminal part of ABD (residues 1–19), the LAEAKVLNRELDKYGVS amino acid sequence was present. Multiple alignment was performed in ClustalW.

REX ligands competitively inhibit p19 subunit binding to the native IL-23 receptor on human cells

To explore whether the REX ligands bind to the native IL-23 receptor molecules on the cell surface, we first investigated cultured human K-562 and Jurkat leukemic cells for the expression of IL-23R. We found that both K-562 and Jurkat cells express IL-23R [Fig. 8(a,b)] and this expression is further increased upon T-cell activation, as documented 24 h after the induction [Fig. 8(c)]. We also found that THP-1 cells express more IL-23R with REX125, REX009 and control ABDwt proteins, respectively. It can be seen that the sensor response to IL-23R-IgG was much higher in the channels coated with the REX proteins than in the reference channel functionalized with ABDwt. Interestingly, the interaction of IL-23R-IgG with the REX variants was very sensitive to pH and salt composition of the running buffer. The complex was stable at pH 5.0 of the sodium acetate (SA) buffer, while it was very rapidly dissociated at pH 7.4 in PBS buffer. Similar results were obtained when IL-23R-IgG was immobilized to the sensor surface and REX proteins were flowed over the sensor (data not shown). The reference-compensated sensor responses to binding of IL-23R-IgG chimera to immobilized REX009, or REX125, respectively, at pH 5 were analyzed using an 1:1 interaction model in the kinetic BiaEvaluation software. Global fit of four concentrations in the range of 20–200nM indicated a dissociation constant $K_d = 5.3 \pm 0.6 \times 10^{-9}$M for REX009. The binding affinity for REX125 could not be precisely determined due to a more complex interaction mode, but it was estimated to be in the order of $10^{-7}$M.

To investigate the thermal stability of the strongest inhibitory binders, we performed the fluorescence-based thermal shift assay (data not shown). Melting temperatures ($T_m$) for REX125 and REX128 were found to be 56 and 56.5°C, respectively, and for REX009 between 50 and 53°C, while the $T_m$ value for WT control was found to be 58°C. This suggested that the randomization of mutable residues of the ABD domain did not significantly affect the basic stability of the scaffold structure.

Figure 5
REX binders compete with the soluble recombinant p19 subunit of IL-23 for binding to immobilized exIL-23R. REX-ToLA-AVI variants were serially diluted in PBST solution containing 20 nM DH-MBP-p19 as ligand of immobilized exIL-23R. Bound p19 was detected with anti-IL-23 (p19) polyclonal antibody sandwich with secondary anti-IgG-HRP. ABDwt-ToLA-AVI, recognizing human serum albumin, served as a negative control. Error bars are shown as standard deviations.

Figure 6
As shown in Figure 6, increasing concentration of REX125, REX115, and REX009 binders decreased the binding of DH-MBP-p19 to the immobilized IL-23R-IgG. A similar inhibitory effect of the REX binders was also found for the recombinant Sf 21 (baculovirus)-derived human single-chain IL-23 (R&D Systems) (not shown). Thus, we conclude that we identified REX variants with the ability to suppress p19/IL-23 binding to IL-23R, as demonstrated in several layouts of direct ELISA.

than K-562, as documented in Figure 9(a) by IL-23R-specific polyclonal antibody and, therefore, both these cell lines were further used as targets for REX ligand-binding assay. As shown in Figure 9(b), all of the tested REX variants bound to K-562 as well as THP-1 cells, and the extent of REX ligand binding correlated well with the observed level of IL-23R expression on the surface of both cell types [Fig. 9(a)]. To further demonstrate that binding of REX ligands correlates with IL-23R expression, we performed a cell-surface binding test with Jurkat cells that express lower amounts of IL-23 receptor per cell than the K-562 cells [Fig. 9(c)]. As shown in Figure 9(d), all tested REX binders exhibited reduced binding to Jurkat cells in comparison with the K562 cells, in agreement with the reduced IL-23R expression on Jurkat cells. These results strongly suggested that the generated REX ligands can bind to native IL-23R molecules exposed on the human cell surface.

To corroborate this observation, we performed assays in which the p19 subunit was allowed to compete with REX ligands for the binding to IL-23R on the cell surface. For this purpose, we used THP-1 cells expressing higher levels of IL-23R [Fig. 9(a)], to which also higher amounts of DH-p19 protein were bound than to K-562 cells [Fig. 9(a)]. As shown in Figure 10(b), at increasing concentrations of the DH-p19 protein, the binding of all

**Figure 6**
REX binders compete with p19 subunit-mediated binding of IL-23 to the IL-23R-IgG receptor chimera. The IL-23R-IgG receptor chimera was immobilized on an ELISA plate and serially diluted inhibitory REX-TolA-AVI ligands were used to compete for binding with 20 nM of DH-MBP-p19. Bound p19 was detected with anti-IL-23 (p19) polyclonal antibody sandwich with secondary anti-IgG-HRP. ABDwt-TolA-AVI served as a negative control. Error bars represent standard deviations.

three tested REX ligands to THP-1 cells was significantly inhibited.

REX binders inhibit IL-23-dependent ex vivo expansion of IL-17-positive CD4+ T-cells

The sum of the above-outlined results indicated that at least several of the generated REX ligands could bind to native IL-23R molecules on human cells and block the p19-subunit-mediated binding of the IL-23 cytokine to its receptor. Therefore, we assessed ex vivo whether the REX ligands could inhibit the IL-23 signaling function on primary human T-cells. We determined whether blocking of IL-23R by excess of REX ligands would inhibit IL-23-mediated expansion of primary human Th-17 lymphocytes. Mononuclear cells were isolated from the blood of healthy donors and stimulated with anti-CD3 monoclonal antibody and co-stimulated by activating antibodies binding CD28 and CD49d in the continued presence of the Th-17 conditioning cytokines IL-23 and IL-2. As shown in Figure 11, over the 3 days of ex vivo cultivation of PBMC suspensions, a marked decrease of Th-17 cell expansion (decrease of counts of IL-17-secreting, IFN-γ non-secreting T-cells) was observed when excess of the REX ligands was present, as compared with mock treatment or presence of the ABD-WT control. In PBMC suspensions, the enhancement of Th17 cells after IL-23-mediated induction is documented as a difference between non-induced cells (sample NO IL-23, 0.52 ± 0.11, n = 6, P = 0.0001) and normalized counts of IL-23 stimulation (IL-23 only, n = 1), shown as a boxplot in Figure 11(b). The addition of ABD-WT as a control into the PBMC suspensions had little effect on Th-17+ cell expansion (0.88 ± 0.26, n = 7, P = 0.2892). In
contrast, all tested REX variants significantly inhibited Th-17+ cell expansion: REX009 (0.62 ± 0.32, n = 7, \( P = 0.0559 \)), REX115 (0.55 ± 0.20, n = 5, \( P = 0.0074 \)) and REX125 (0.42 ± 0.17, n = 5, \( P = 0.0004 \)), as documented in Figure 11(b).

To verify whether the observed inhibitory effect of REX binders in PBMC suspensions can be attributed to the T-cell-dependent cell expansion, we repeated the same experiment in samples with separated T cells isolated from the same PBMC donors. As shown in Figure 11(c), the IL-23-dependent Th-17+ cell count enrichment was also detected (NO IL-23, 0.77 ± 0.08, n = 4, \( P = 0.0116 \)). T-cell suspensions with added ABD-WT control exhibited no inhibitory effect on T-cell expansion (0.99 ± 0.26, n = 4, \( P = 0.9901 \)). In striking contrast to this observation, REX variants demonstrated an immunosuppressive effect on T-cell expansion as follows: REX115 (0.69 ± 0.17, n = 3, \( P = 0.0883 \)), REX125 (0.65 ± 0.16, n = 3, \( P = 0.0671 \)) and REX009 (0.80 ± 0.01, n = 2, \( P = 0.0139 \)).

In summary, the collected data indicate that the tested REX variants inhibited IL-23-dependent Th-17+ cell expansion to the level of no-IL-23-induced samples (REX009) or even below this level (REX115 and REX125) and this finding is valid for both PBMC and separated T-cell samples. While IL-23 was shown to promote development of Th-17+ T-cells in man, the mode of its action might be fixing the Th-17 commitment rather than “de novo” Th-17 development, survival or proliferation enhancement. As shown here, REX ligands might block the IL-23 signaling function on human T-cells through selective binding and occupation of the IL-23 receptor.

**DISCUSSION**

In this work, we aimed to generate novel immunomodulatory binders suppressing the function of human IL-23 receptor, a crucial molecule of the IL-23-mediated signaling pathway. As a valuable alternative to conventionally developed neutralizing antibodies, we thought to use the three-helix bundle scaffold-derived combinatorial library of albumin-binding domain variants as a primary source for selection of IL-23 receptor binders. To this goal, we used our recently constructed high complex library that has been successfully used for selection of high-affinity binders of human IFN-\( \gamma \). Using campaigns of ribosome display selection, we generated 18 sequence variants of high-affinity IL-23R binders, much less in comparison to the selection of high-affinity binders described before, suggesting that a limited number of high-affinity epitopes were available as targets. This is further supported by a high redundancy of the found REX variants demonstrating that the selected high-stringency conditions used for high-affinity binder screening in ribosome display were properly adjusted. Among the 18 found sequence variants, 11 were observed to inhibit binding of p19 to the bacterial product of human IL-23R, suggesting that several surface-exposed epitopes are critical for the ligand-receptor interaction. Among seven best inhibiting clones, two (REX001 and REX009) contain a randomized cysteine residue located in the inter-loop between helices 2 and 3 (residues 29, 30). Another of the best inhibitory clones, REX125, includes an interesting randomized sequence pattern 24W-27P-29R-30R-32R-33P-36W with an intrinsic
symmetry 24W-27P-30R-33P-36W between helices 2 and 3 that could be beneficial for the ligand binding. In addition, proline residues are known to break α-helical structures, so this may lead to a changed ABD scaffold geometry, affecting C- and N-terminal ends of the helices 2 and 3, respectively, and thereby to an increased flexibility of the inter-loop, supporting the binder’s affinity. Yet the detailed molecular structure of REX-IL-23R complexes needs to be further investigated, and installation of proline residues in amino acid positions 27–29–30–32–33 in the case of all the best inhibitory binders (REX009, REX115, REX125, REX128) attracts attention as cysteine and proline residues are being typically designed to be eliminated from the randomization during the combinatorial library construction.

Interestingly, the REX005 binder was found to inhibit the binding of the p19 protein to the used bacterial receptor products. This inhibitory effect was then confirmed in competition ELISA using a 46 amino acid synthetic form of ABD (not shown), excluding the possibility that the TolA spacer protein affects the binding or inhibition. However, this clone does not bind to cell-surface IL-23R expressed in THP-1 and K-562 cells. It is possible that glycosylation of the Ig-like domain in the N-glycosylation consensus (residues 29, 47, and 81) or in the distal FnIII domain (residues 141 and 181).

Figure 11
REX binders inhibit IL-23-dependent ex vivo expansion of IL-17-producing CD4+ T-cells. PBMCs from seven healthy volunteers were activated using anti-CD3 and co-stimulation in the presence of IL-23 and IL-2 and in the presence or absence of indicated REX ligands for 3 days. (a) Detection of IL-17-producing cells that were gated using FSC, SSC, CD3+, and CD4+. The number in the right-hand bottom corner indicates the percentage of the gated cell population producing solely IL-17 (IFN-γ secretion marks TH1 type response). (b, c) The amount of IL-17-producing cells recovered from PBMC (b) or separated T-cell (c) samples of healthy donors after 3 days of activation in the presence or absence of the REX ligands. Total cell numbers were normalized to cell counts in IL-23/IL-2-treated samples. Boxes range from 25th to 75th percentiles with a line at the median. Whiskers reach 10th and 90th percentiles. Outlying values are indicated as individual circles.
prevents the binding to the cell-surface receptor. However, we cannot exclude that REX005 recognizes an unnatural epitope found in the bacterial receptor protein, yet this binder interacts with the cytoplasm-produced E. coli Shuffle strain as well as periplasm-targeted BL21 (λDE3) cell products.

To demonstrate that REX binders recognize cell-surface IL-23R, we thought to prepare cell transfectants expressing human IL-23R on the cell surface. To this goal we tested several different cell lines and found that all of them, including K-562, Jurkat, THP-1, HEK 293, COS-7, or CHO cells, to some extent bind anti-IL23R antibodies. In addition, several other human cell lines such as HeLa, A431 and NKT, or mouse NIH 3T3 cells, have been described to express IL-23R. Therefore, we decided to demonstrate specific binding of the generated REX variants using the correlation of cell-surface REX binding with IL-23R expression, in combination with a p19-specific competition binding assay. We clearly demonstrated high-affinity binders with immunomodulatory function. To our knowledge, this is the first example of described ABD-derived receptor antagonists with ex vivo immunosuppressive function. The unique REX inhibitory binders might be a useful clue for designing novel anti-IL-23R-based therapeutics, especially when the precise structural mode-of-function of the IL-23R complex is not available. In addition, the small 5 kD size of the ABD domain brings new alternatives for skin-penetration-based drug delivery systems that might be essential for psoriasis treatment.
